

Abstract

This application note discusses the control of a 3-phase brushless BLDC motor in Sinusoidal PWM Modulation mode using Zilog's Z8FMC16 Series of microcontrollers. This Z8FMC16 Series is designed specifically for motor control applications, featuring an on-chip integrated array of application-specific analog and digital modules. The result is fast and precise fault control, high system efficiency and on-the-fly speed/torque control, and ease of firmware development for customized applications.

This document further discusses ways in which to implement sinusoidal PWM modulation and phase-angle synchronization with Hall sensor feedback. The results are based on using a modified version of the Z8FMC16 Series Modular Development System (MDS) Module, a 3-phase motor control (MC) application board, and a 3-phase 24VDC, 30W, 3200 RPM BLDC motor with internal Hall sensors.

- **Note:** The source code file associated with this application note, [AN0361-SC01.zip](#), is available free for download from the Zilog website. This source code has been tested with version 5.0.0 of ZDSII for Z8 Encore! MCUs. Subsequent releases of ZDSII may require you to modify the code supplied with this application note.
-

Features

This application offers the following power-saving features:

- Smooth motor start-up with reduced starting current
- Sinusoidal PWM modulation feedback from three Hall sensors
- Microcontroller-based overcurrent protection
- Adjustable speed and current (frequency and sine magnitude)
- Selectable control of motor direction
- UART interface for PC control
- LED to indicate motor operation
- LED to indicate UART control
- LED to indicate a fault condition

Figure 1 shows a block diagram of the Z8FMC16 Series MCU architecture.

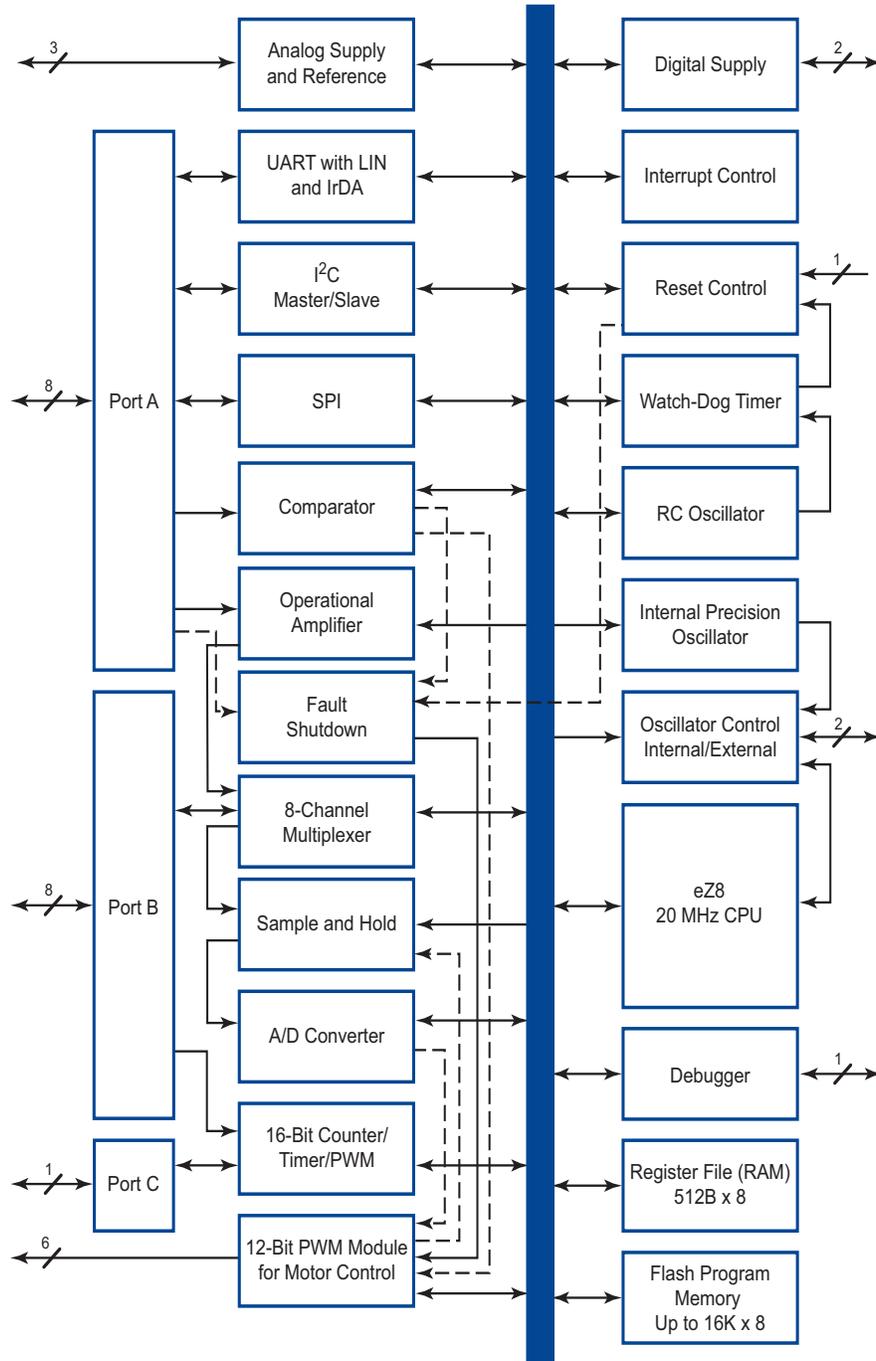

Figure 1. The Z8FMC16 Series MCU Architecture

Discussion

The Z8FMC16 Series Flash microcontrollers upon which this Sinusoidal PWM driver has been conceived are based on Zilog's advanced 8-bit Z8 Encore! CPU core. The Z8FMC1600 MCU, which is based on this core, sets the standard for performance and efficiency with a 20MHz external clock that operates at a minimum of two clock cycles per instruction.

Up to 16KB internal Flash memory is accessible by the CPU to improve processor throughput. Up to 512 bytes of internal RAM provides storage of data, variables and stack operations.

PWM sinusoidal operation has certain advantages over block-commutated PMSM motor driving approaches, most notably its lower electrical and lower acoustical noise signatures. By comparison, the block commutation method causes harsh current transitions through the PMSM motor coils, essentially turning the phase windings of the motor on and off between commutations. The PWM sinusoidal method does not create these harsh current transitions through the motor coils, because the current and phase voltages are sinusoidal in nature. Motors operating via the sinusoidal PWM method, however, typically run at a higher efficiency than block-commutated motors.

Because of the advantages of a PWM sinusoidal driver scheme's attributes, PWM sinusoidal operation can be a better option for certain applications in which the life of ripple capacitors, ball bearings, and electrical noise are concerns.

Sinusoidal PWM driving schemes can be used to drive either PMSM- or BLDC-type motors, however, to take advantage of a sinusoidal driving scheme, a PMSM-type motor is likely to demonstrate the best results due to its sinusoidal wound-phase wiring.

This application implements a third harmonic injected sine wave which utilizes approximately fifteen percent more of the available bus voltage. Therefore, the third harmonic injected sine wave modulation approach has the same bus voltage utilization as the space vector modulation approach.

In each of the Z8FMC16 Series products, the novel Z8 Encore! device architecture allows for the realization of the following enhanced control features. Each is described in the following sections.

- Time stamp for speed control
- Integrated operational amplifier
- Multichannel PWM timer

Time Stamp for Speed Control

The capture feature of the 16-bit timers can be used to take a time stamp of the Hall sensor's electrical timing periods. Upon a predefined Hall state, the asynchronously operating timer is read and its value is compared against a calculated speed reference value using PI closed loop control.

Integrated Operational Amplifier

Appliance controllers almost invariably monitor motor speed by sensing current through the motor windings using sensor and sensorless techniques in conjunction with the ADC. Ordinarily, sampling instances by the ADC are synchronized by the MCU. With this process, an external operational amplifier is often used to convert the current signal to a voltage signal; the ADC next samples the voltage signal and outputs the result to the processor. The processor then synthesizes the PWM outputs to control motor speed. In the case of the Z8FMC16 Series of microcontrollers, an on-chip integrated operational amplifier eliminates the requirement for an external component, thereby reducing overall system cost.

Multichannel PWM Timer

Each Z8FMC16 Series MCU features a flexible PWM module with three complementary pairs – or six independent PWM outputs – supporting deadband operation and fault protection trip input. These features provide multiphase control capability for a variety of motor types and ensure safe operation of the motor by providing immediate shutdown of the PWM pins during a fault condition.

Theory of Operation

In a brushless DC motor, the rotor is comprised of permanent magnets, while the stator windings are similar to those in polyphase motors.

Generally, there are two methods for determining motor position and speed, sensored control and sensorless control. In sensor-based control applications, the Hall elements are integrated into the motor and used to detect the position of the rotor for drive and sine wave synchronization. In contrast, sensorless control employs the detection of back-EMF (BEMF) signals, which are generated (induced) by specific phase windings to synchronize the timing of a control loop.

An inverter bridge is used to drive the PWM sine generated currents through the BLDC motor windings, as shown in Figure 2.

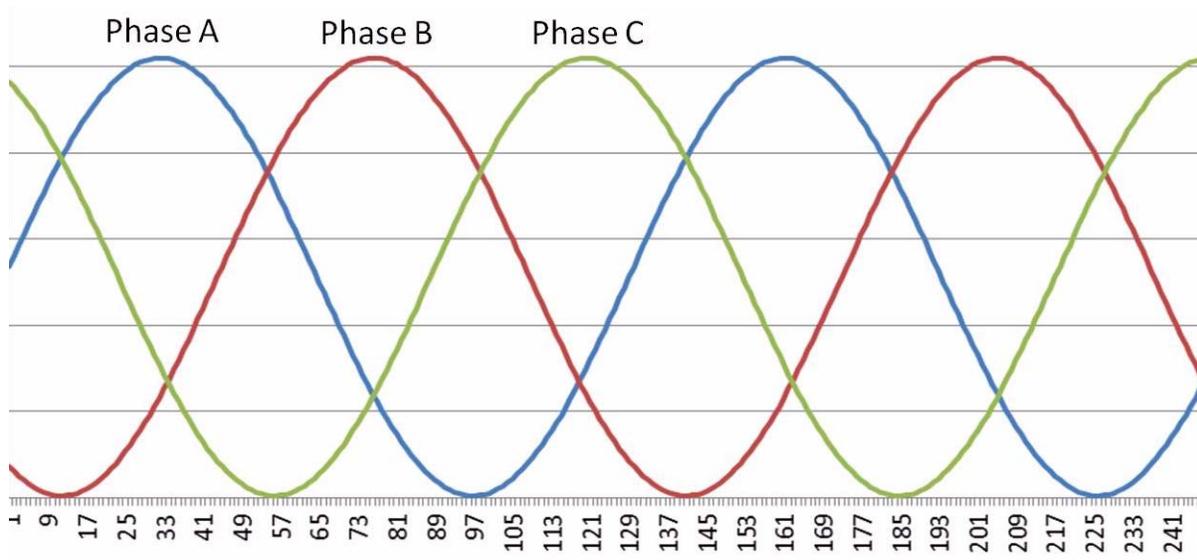

Figure 2. 3-Phase BLDC Motor Control System

The algorithm for Hall sensing is based on an implementation using three I/O ports which are configured for an *interrupt on edge* change of the Hall sensor's signals. One of the advantages of using Hall sensors is that the angular position of the motor is known upon startup of the motor, therefore minimizing erratic start-up functionality and the requirement for a start-up ramp until BEMF zero crossings are detected. The PWM duty cycle presents at the motor windings then produces the torque to start the motor. The rotating motor generates the Hall signals that vector into a single I/O service interrupt routine, which determines the next commutation state.

Another advantage using Hall sensors as opposed to BEMF sensing is that under sudden and strong load increase, the information of the commutation angle is not in jeopardy of becoming lost. In sensorless feedbacks, an extreme load increase can cause an inductive spike – which results from the stored magnetic energy of the previously turned off phase – to become wide enough to suppress the BEMF information. As a result, the commutation angle information can be lost and could cause the motor to stall.

The Hall sensor's angular position provides the information to energize all three phase voltages at the correct commutation angle. As opposed to trapezoidal or block commutation, in which two of the three phases are energized for each commutation step, the sinusoidal commutation requires all three phases to be energized for each commutation step, as shown in Figure 2.

To save computation time, the firmware implements a look up table in which the sine values are stored. The PWM-timer-interrupt-service-routine interrupts every 50 μ s and is used to fetch the sine values from the sine table and update the PWM sine frequency for Phase A, Phase B, and Phase C. This method provides very regular time intervals to update the sine frequency and scaling of the sine magnitude for all three phases. Right before exiting

the PWM timer interrupt service routine, these three PWM channels are updated with the new PWM modulation values.

For this application, a PWM timer frequency of 20kHz was chosen to minimize linear switching power losses in the MOSFETs, and to be out of the audible noise range.

PWM Frequency Calculations

Using every value in the 256 sine array, the frequency is:

$$\frac{1}{(\text{PWM period} \times 256)} = \frac{1}{50\mu\text{s} \times 256} = 78.125\text{Hz}$$

If every second sine value is used instead, then the frequency is effectively doubled and becomes:

$$\frac{1+n}{(\text{PWM period} \times 256)} = \frac{2}{50\mu\text{s} \times 256} = 156.25\text{Hz}$$

In the second PWM frequency calculation equation, the numerator represents the 1 + nth number of an offset to the array elements; the larger the numerator, the higher the sine frequency. A better way of obtaining a wider sine frequency range and resolution of the sine wave is to use a 16-bit integer-type sine index of which only the upper byte is used to fetch the next PWM sine value from the look-up table. Depending on the frequency demand, the values of the upper byte can change with higher granularity, hitting each sine array value more or less times while the sine index continuously rolls over. Using this method, the lowest period using a 16-bit pointer to a 256-element sine table is:

$$65535 \times 50\mu\text{s} = 3.277 \text{ seconds}$$

Assuming the sine frequency is 60Hz, the offset value for the sine table pointer is:

$$\text{SineIndexOffset} = \frac{60 \times 65536}{20000} \approx 196$$

The resolution of the generated sine wave is a function of the sine frequency.

Sine and Hall Commutation and Frequency Adjustment

Hall sensor interrupts are generated six times – once every sixty degrees – therefore providing data about the rotor position which is used to synchronize the sine wave commutation angle and frequency with the Hall commutation angle and frequency.

[Figure 2](#) on page 5 illustrates the generation of three 120-degree shifted sine waves based on values from a look-up table (LUT) which are then reconstructed in the PWM interrupt service routine.

Speed Calculations

The angular period times of the rotor are captured every one-sixth of an electrical commutation, wherein Timer0 represents the number of timer ticks. These timer ticks are then compared against the demand speed coming from a potentiometer – also represented in timer ticks – and processed in a PI closed loop to adjust the look-up table values to change the frequency of the motor. If the motor is operated with open-loop speed control, then the speed demand coming from a potentiometer is used to directly generate the look-up table (LUT) values to change the motor frequency.

The angular speed calculation is:

$$\omega = \frac{d\theta}{dt}$$

In this equation, $d\theta$ is the angular displacement, and dt is the delta time taken for the angular displacement.

The position information is provided by the Hall sensor binary state, and the time between angular positions is measured by Timer0 timer ticks.

The frequency of a sinusoidal operated motor is calculated using the following equation:

$$F(\text{rotor}) = \text{RPM} * \frac{p}{120}$$

The rotor frequency becomes:

$$F(\text{rotor}) = \frac{p/2}{\text{Measured ticks} * \text{timer resolution} * \text{commutation steps} * 60}$$

$$\text{RPM} = (120 * f) / N$$

In the above equation, N is the number of pole pairs and f is the frequency.

Figure 3 illustrates how these calculations can influence PWM sine operation of a 3-phase BLDC motor.

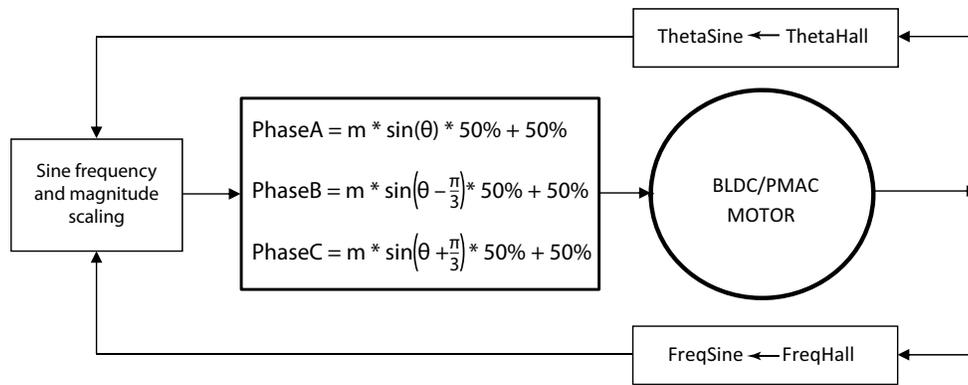

Figure 3. Simplified PWM Sine Operation of a BLDC Motor

The hardware used to realize the sinusoidal PWM motor driver approach discussed in this section is shown in the block diagram in Figure 4.

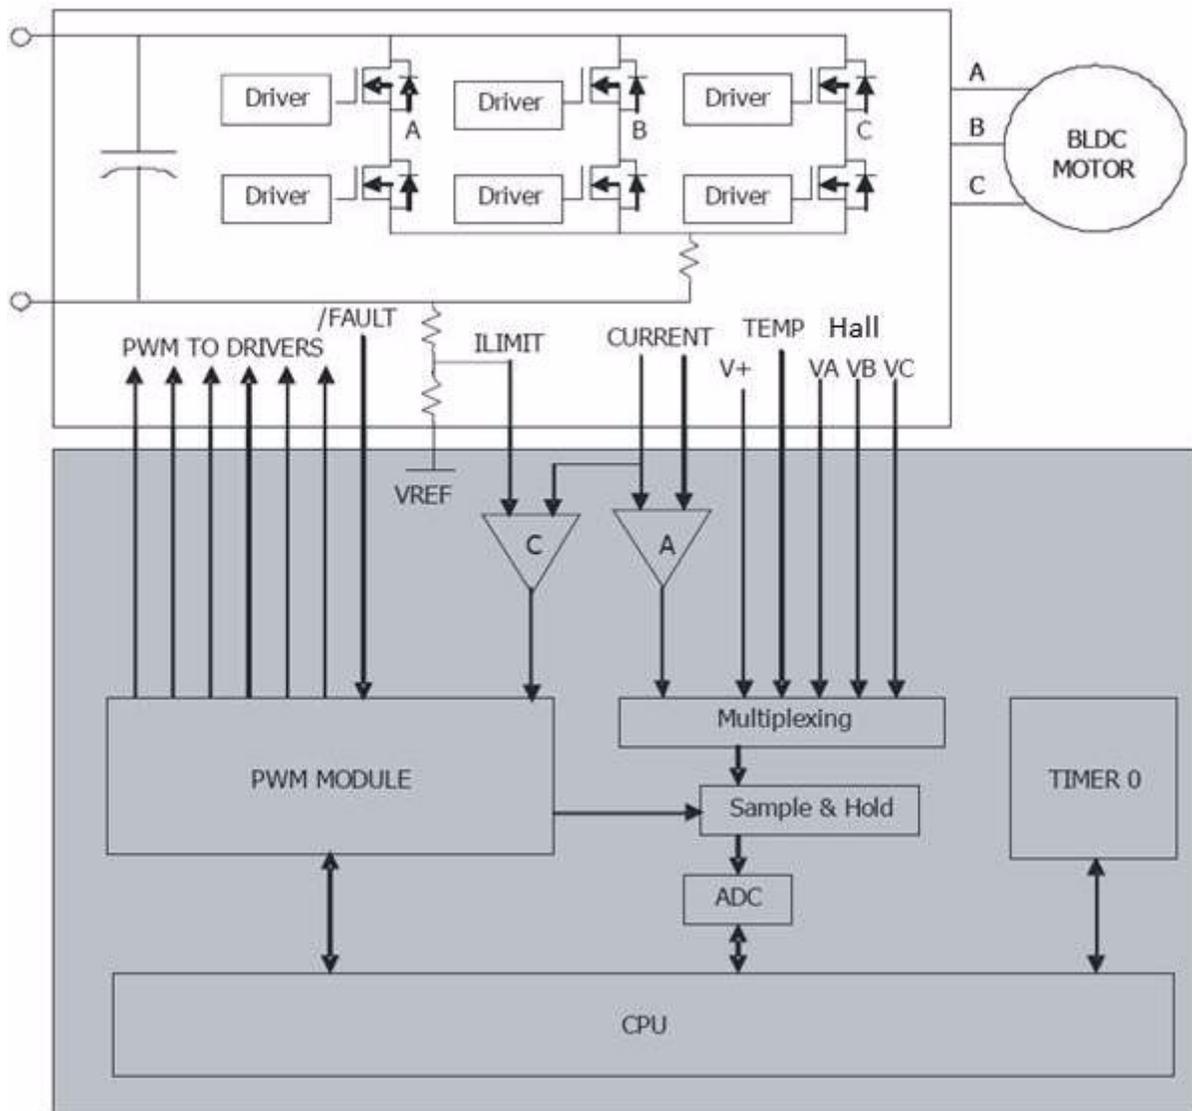

Figure 4. 3-Phase BLDC Motor Control System

Overcurrent Protection

Currents can reach excessive amounts during startup, load changes, or catastrophic failures, for which a motor and electronics must be protected. A key feature of the Z8FMC16 Series MCU is the direct coupling of the on-chip integrated comparator to the PWM module to enable a fast, cycle-by-cycle shutdown during an overcurrent event. Oscilloscope-generated waveforms representing this sequence of events are shown in Figure 5.

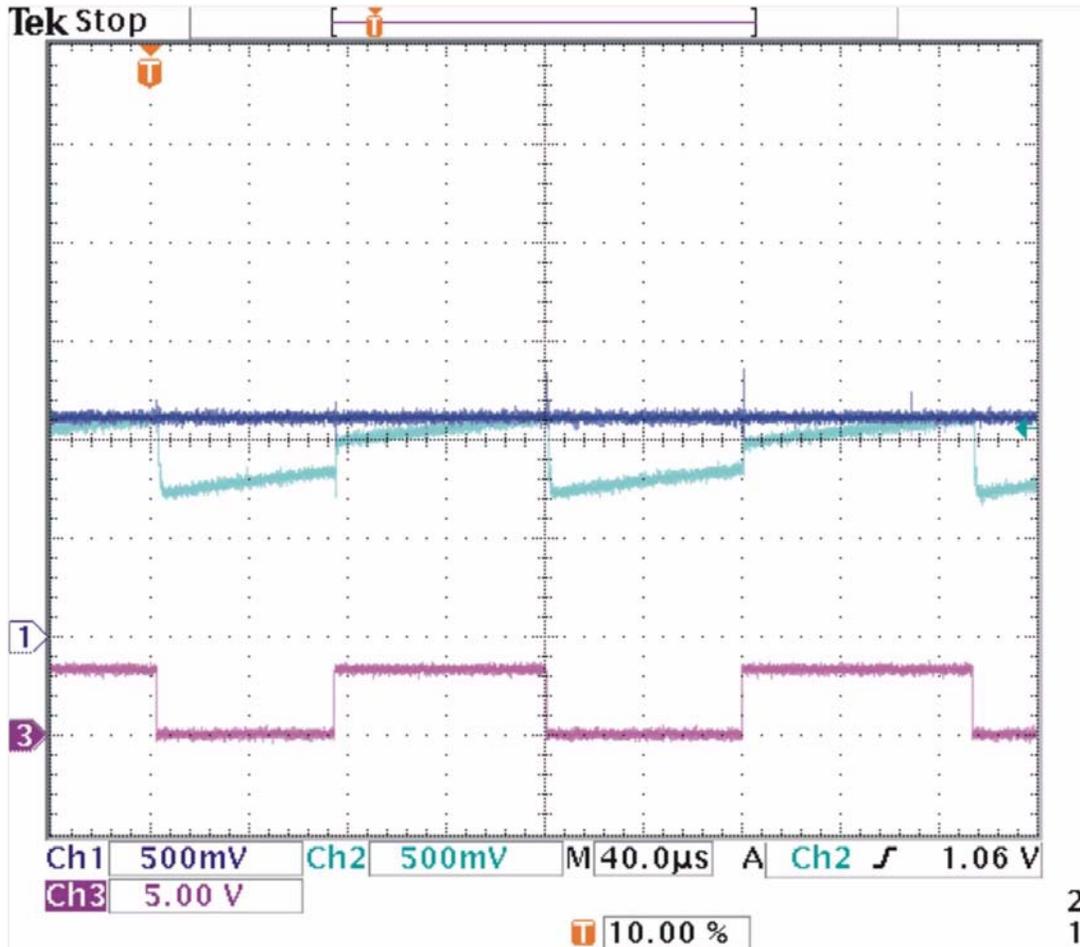

Figure 5. Cycle-by-Cycle Shutdown

Testing

This section describes how to run the code and demonstrate this sensored brushless DC motor application including its setup, implementation and configuration, and the results of testing.

Equipment Used

The tools and firmware that are used to operate this BLDC Motor Control application are listed below.

- Z8FMC16 Series Motor Control Development Kit (Z8FMC160100KITG)
- Optoisolated USB SmartCable
- ZDS II – Z8 Encore! version 5.0.0
- PWM sine driver firmware ([AN0361-SC01.zip](#))
- 24 V power supply
- 30 W Linux BLDC motor
- Optional equipment:
 - Digital oscilloscope or logic analyzer
 - Tektronix A6302 current clamp
 - 3.8 V/K_{RPM} Class-F Permanent Magnet Synchronous Motor (PMSM) motor

Hardware Setup

The BLDC Motor Control application code developed for this application was tested with a modified version of the 3-phase demo control module contained in the Z8FMC16 Series Motor Control Development Kit. Figure 6 shows the application hardware connections.

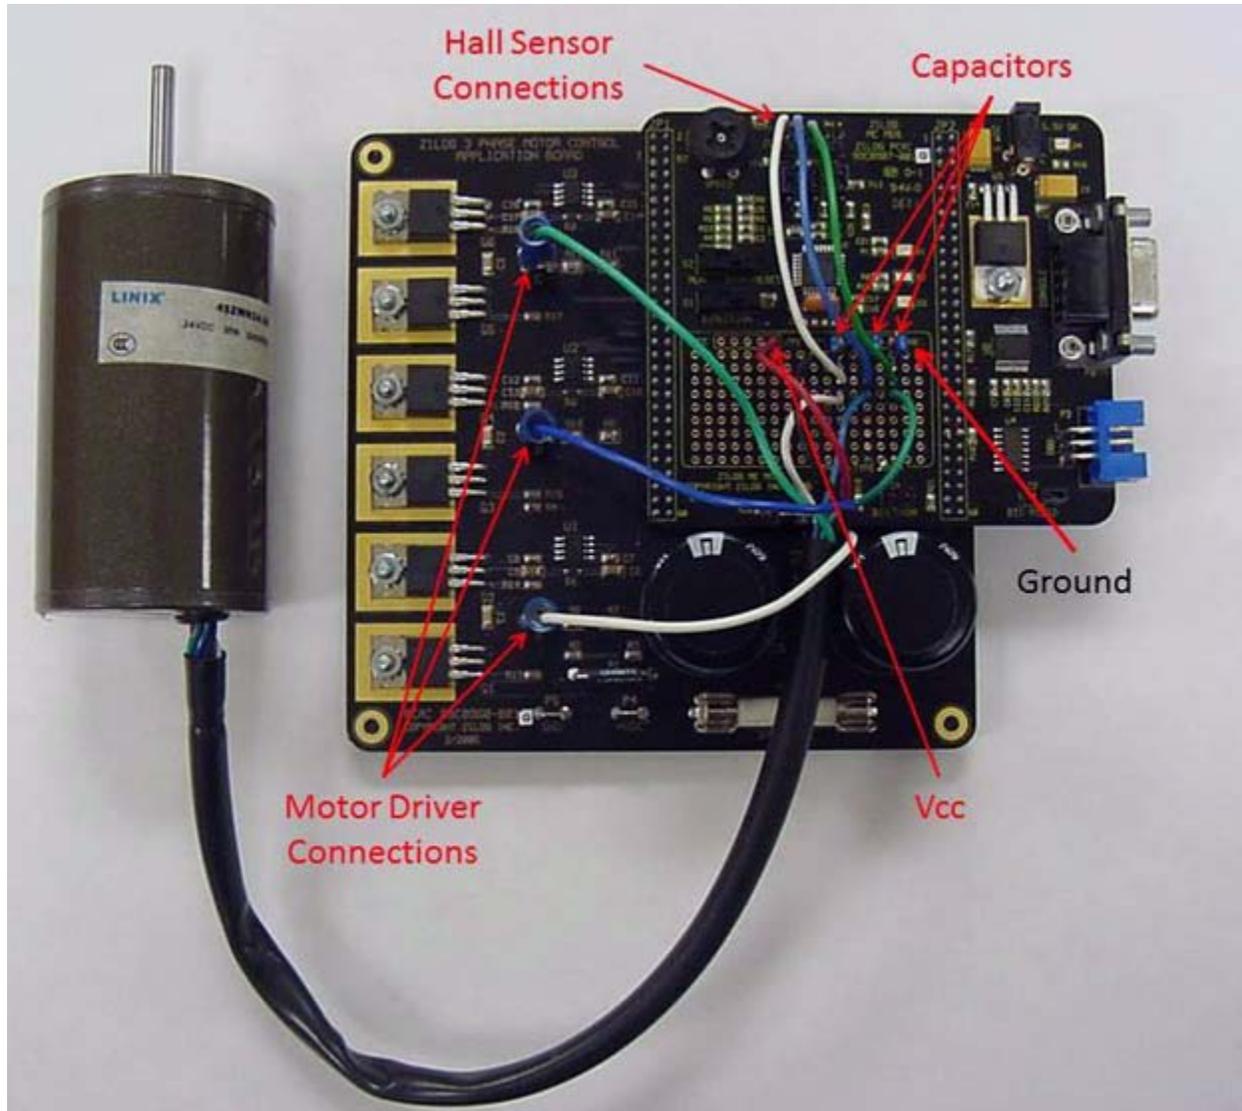

Figure 6. Demo Control Module with a Linix 30W BLDC Motor

Testing Procedure

Observe the procedures in the next two sections to test/demonstrate the BLDC Motor Control on the Z8FMC16 Series MCU using Sensored Sinusoidal PWM Modulation.

Connect the Motor to the Demo Control Module

The MDS Module's prototype area can be used to simplify circuit modifications. To build, configure, and test the hardware and firmware for this application, complete the following modifications. Refer to [Figure 7](#) on page 13 and/or to the schematic diagram in the [Sensor-](#)

[less Brushless DC Motor Control with Z8 Encore! MC Microcontrollers Application Note \(AN0226\)](#) for assistance.

1. Connect the black Hall sensor supply wire to Ground (TP1).
2. Connect the red Hall sensor supply wire to V_{CC} (TP2).
3. Connect the white Hall sensor wire to PB0 (J1, pin 2).
4. Connect the green Hall sensor wire to PB1 (J1, pin 4).
5. Connect the blue Hall sensor wire to PB2 (J1, pin 6).
6. Place jumpers J4, J5, and J6 in positions 1-2 to allow proper Hall sensor signal routing from the motor through header J1 to the Z8FMC MCU.
7. Add a 680pF capacitor between each Hall sensor input and ground.
8. Connect the white motor phase wire to P1-A.
9. Connect the blue motor phase wire to P2-B.
10. Connect the green motor phase wire to P3-C.

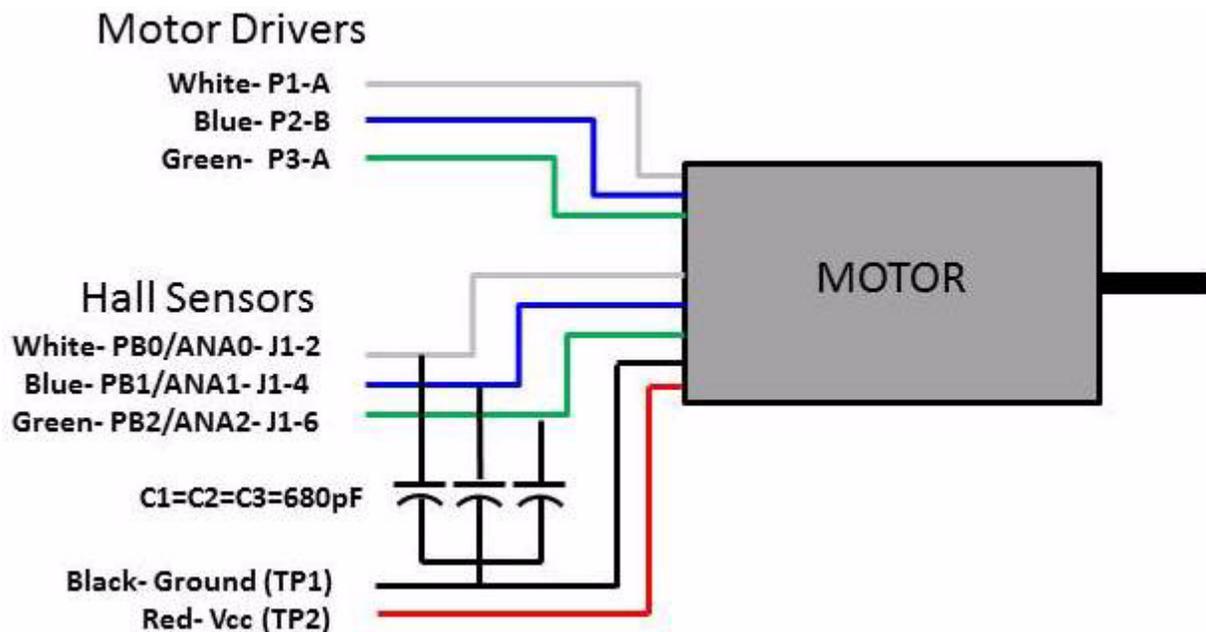

Figure 7. Motor Connections

► **Note:** The 20 gauge motor phase wires are slightly wider in diameter than the 22 gauge Hall sensor wires.

Downloading and Running the Firmware

1. Download the [AN0361-SC01.zip](#) source code file from the Zilog website and unzip it to a convenient directory on your PC's hard drive.
2. Connect the optoisolated USB SmartCable to the PC and to the Demo Control Module to P3 with the ribbon cable.
3. Launch ZDSII for Z8 Encore! and open the project file that is contained in the AN0361-SC01 folder that you downloaded to your hard drive in [Step 1](#).
4. Compile and run the code on ZDSII.
5. Open a terminal emulation console such as HyperTerminal or Tera Term and configure it to the following settings:
 - 57600 baud rate
 - 8 data bits
 - no parity
 - 1 stop bit
 - No flow control
6. Connect the current probe clamp to one of the three motor phase wires to view the sine current.
7. Connect an oscilloscope probe between R9 and R10 on the Demo Control Module to view the sine voltage.
8. From the ZDSII toolbar, click the **Go** button in to start the motor.
9. Control the speed of the BLDC motor with the potentiometer located on the Demo Control Module.

Results

Linux BLDC-type and Teknik/Hudson PMSM-type motors were tested to compare their corresponding voltage and current waveforms. During operation of the BLDC motor, three oscilloscope probes were connected to the BEMF voltage dividers, and one oscilloscope channel was used to monitor one out of three current wave forms with a current probe. The scope channel was set to AC so that the positive and negative half of the sine wave modulate with respect to the midpoint. These three voltages and one current waveform are shown for the BLDC and PMSM motors in Figures 8 and 9, respectively. A characteristic of the third harmonic sine wave is the saddle shape on the top and bottom of the wave.

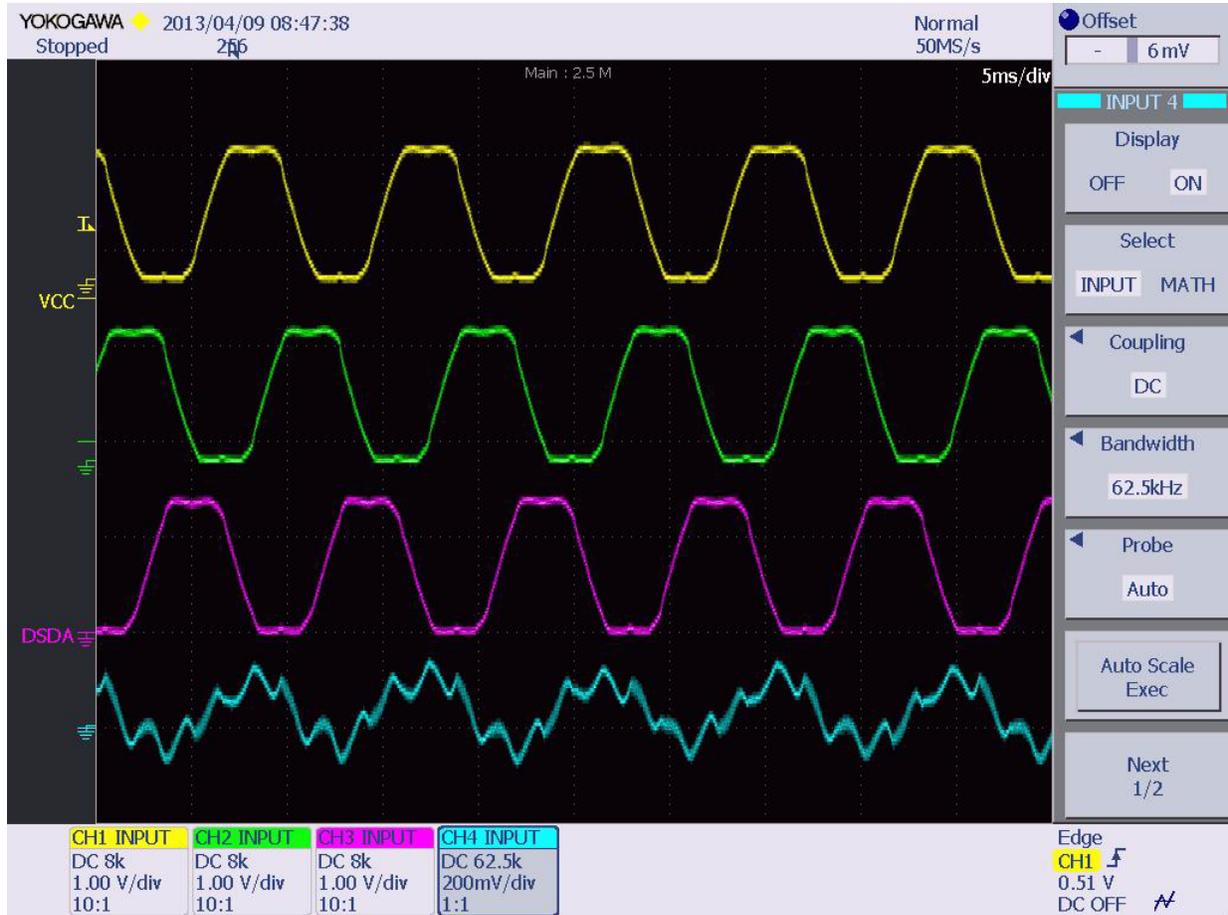

Figure 8. Linux BLDC Motor Phase Voltages and One Current Waveform

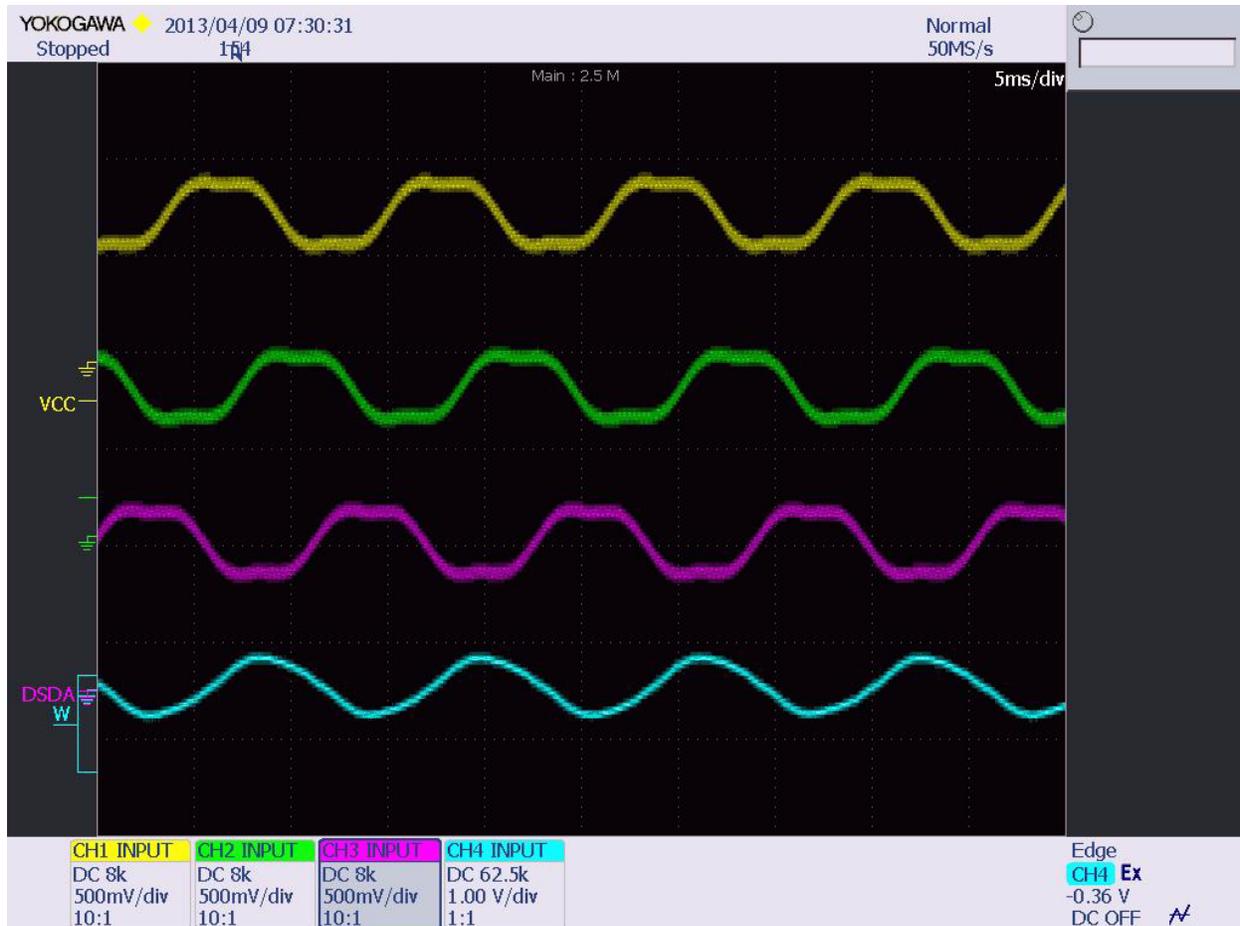

Figure 9. Hudson-Teknic PMSM Motor Phase Voltages and One Current Waveform

Speed Control Performance in a Closed Loop

To monitor performance of the speed control function while operating in a closed loop, the motor speed was set to 2000RPM at a nominal operating voltage of 24V. As this operating voltage was increased and decreased by plus and minus 4V, motor speed was observed to remain constant. To test the PI loop under load, the motor load was increased, which caused the PI to quickly ramp up the current to maintain the set speed. PI loop stability was verified by observing the voltage sine wave while loading the running motor, a condition for which the sine wave period time must be maintained constant in both amplitude and frequency.

Speed Control Performance in an Open Loop

To monitor performance of the speed control function while operating in an open loop, the motor speed was set to 2000RPM at a nominal operating voltage of 24V. As this operating voltage was increased and decreased by plus and minus 4V, motor speed was observed to

vary. The motor load was then increased, which caused the motor current to be increased while its speed slightly dropped.

Summary

The purpose of this application was to demonstrate the operation of a BLDC or PMSM type machine using the sinusoidal PWM technique with the Z8FMC16 Series MCU.

To generate sinusoidal voltages and currents 120 degrees apart for a BLDC machine, a sine Look Up Table (LUT) was implemented to reconstruct the three sine waves and formulas have been shown to calculate the motor frequency. Because the frequency calculations include the PWM period, all sinusoidal wave constructions are executed in the PWM interrupt service routine. The execution time for the sine wave reconstruction in the PWM service interrupt routine takes 20 μ s. The execution time of the Hall interrupt service routine takes 30 μ s. Both execution times are based on a 20MHz external clock.

To maintain synchronization and commutation angle between the sine frequency and hall frequency, the Hall interrupt service routine captures the binary Hall state upon each interrupt and fetches the corresponding reference angle from a Look Up Table (LUT).

The high byte of the PWM sine Look Up Table index is used to fetch the next value from the Sine Look Up Table (LUT). Larger or smaller offsets to this high byte can increase or decrease the frequency of the sine wave.

Sinusoidal PWM operation has the advantage of commutating the BLDC or PMSM with less acoustical and electrical noise, because the sine current through the windings has no steep current transitions due to its sinusoidal currents. This allows for higher life expectancy of ripple current capacitor and ball bearings because the sinusoidal commutation approach causes virtually no torque or current ripple in a PMSM or BLDC type motor. In addition to electrical and acoustical noise reduction, the PWM sine approach also increases the efficiency in a BLDC-/PMSM-type motor. The bus utilization can be further increased if a third harmonic is injected into the PWM sine wave, which can utilize about 15% more of the bus voltage.
